

# Risk Assessment and Cost Benefit Analysis for Pipelines Buried in Slow-Moving Landslides

Michael Porter  
Joel Van Hove  
Owen Bunce  
Pete Barlow

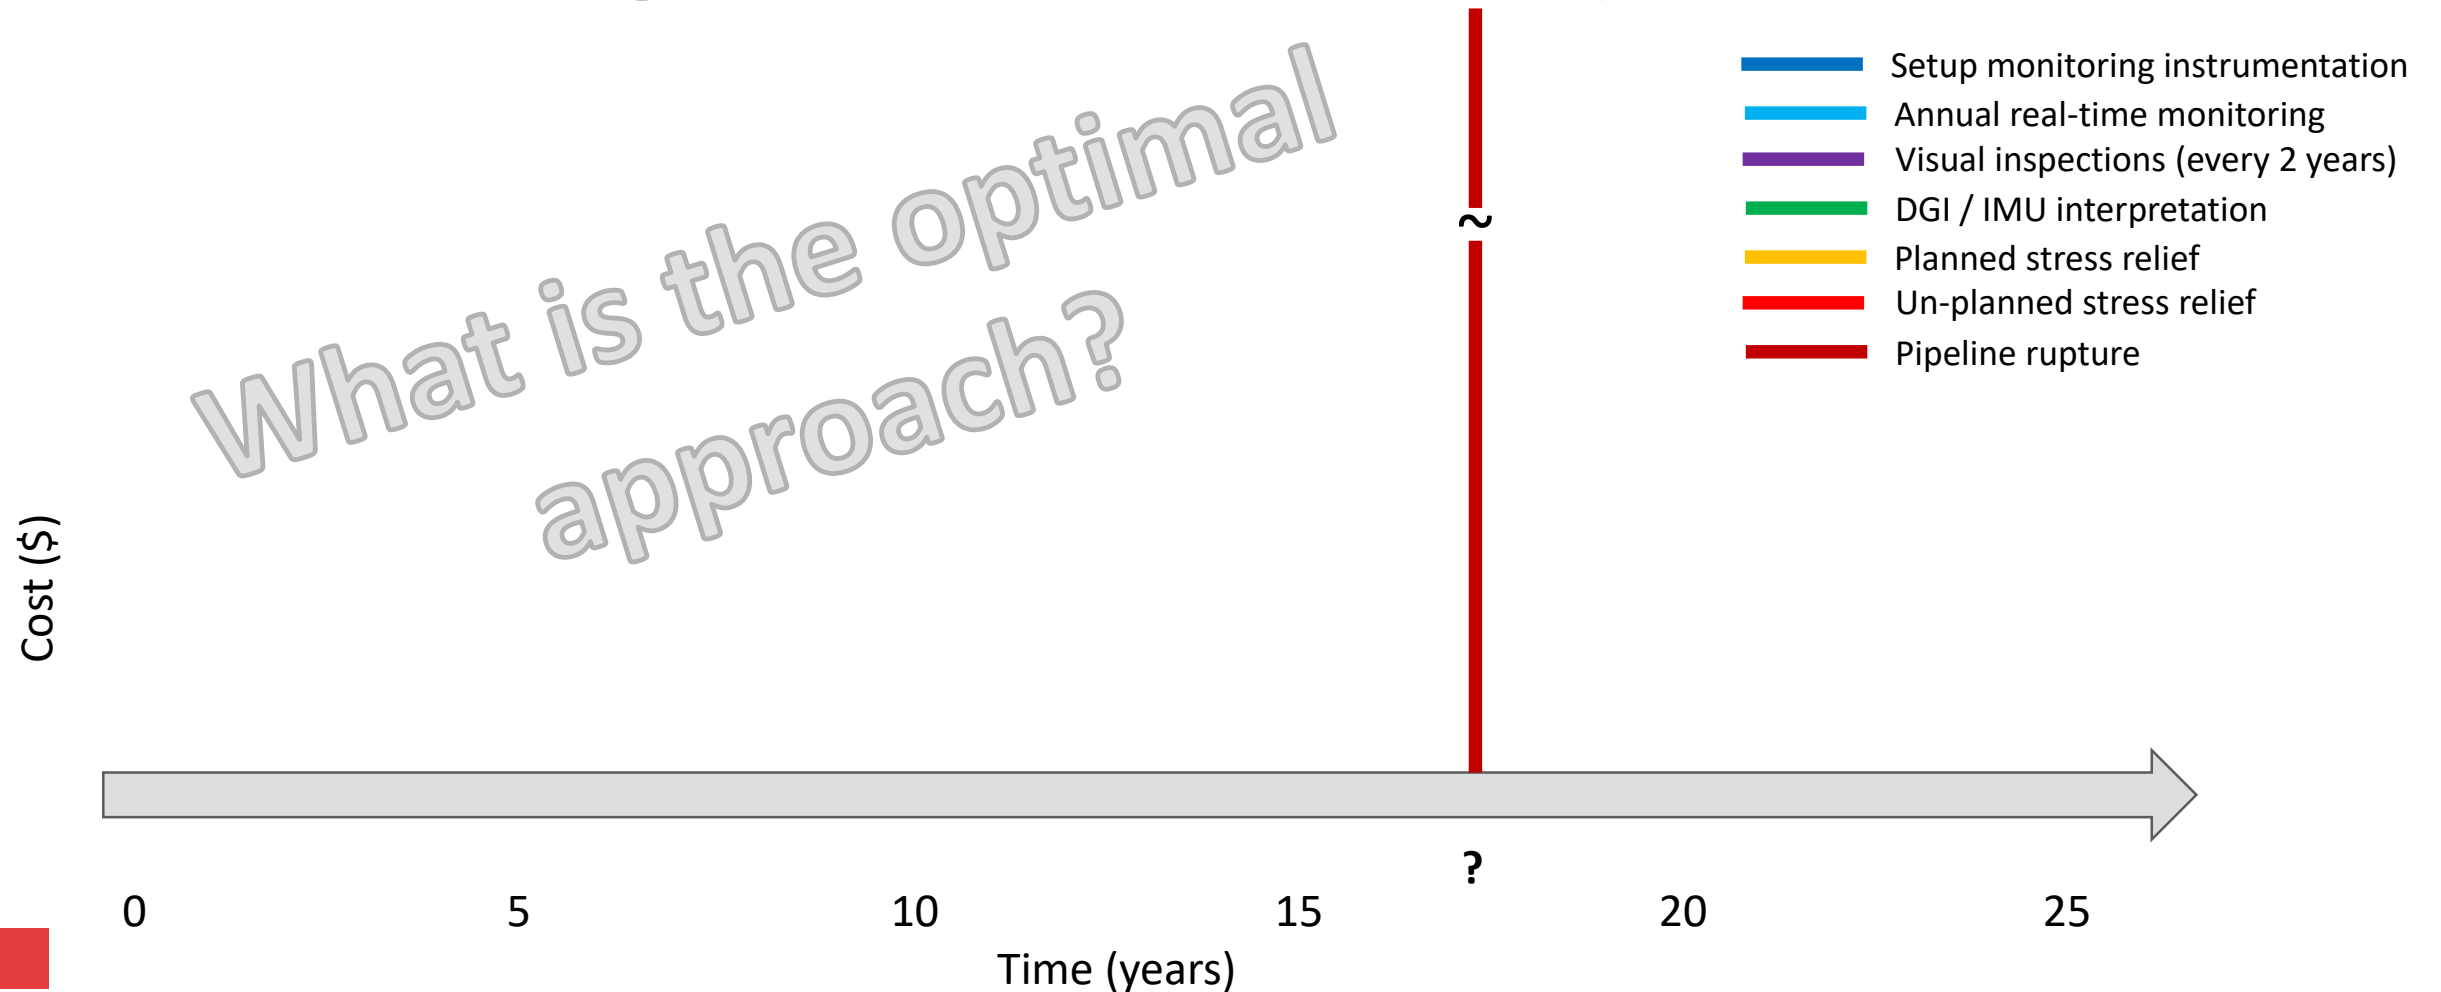

## Management Cost – Very Proactive

## Management Cost – Purely Reactive

## Risk-informed Decision Making

An approach to achieving objectives while balancing costs and benefits in the face of uncertainty

### Examples:

- Clarifying decision-making processes
- Selecting preferred options
- Optimizing solutions
- Prioritizing resources to reduce uncertainty and manage risk
- Emergency preparedness & contingency planning
- Comparing calculated probability of failure or risk against tolerance criteria

## Cost Benefit Analysis & Lifecycle Cost

- Methods of weighing the expected costs and benefits of options
- For decisions about landslide risk management:
  - Cost of planned management effort (e.g. inspections, monitoring, slope maintenance, pipeline maintenance, re-routes)?
  - Expected cost of the residual risk (pipe damage, unplanned outage, pipe rupture)?

present value of residual risk

present value of risk management effort

## Expected Cost of Residual Risk

- Probability x Consequence = Expected Annual Risk Cost
  - Included as annual costs in the cash flow model for lifecycle cost
  - “Easy” if probability is expected to remain constant over design life

## Buried Pipe + Moving Landslide = Complex Dynamic System

- Landslide condition state may change

- Pipeline condition state will change if the landslide moves
  - No Strain → Elastic Strain → Plastic Strain → Loss of Containment

## Lifecycle Costs for Infrastructure Crossing Slow-moving Landslides

1. Define a set of *Asset Condition States* & costs that can be linked to landslide velocity or total landslide displacement
2. Modify a common landslide velocity classification system so that *Landslide Velocity Classes* can be treated as Markov Model condition states
3. Develop *Markov Chain Models* to predict landslide velocity class probability distributions for a range of *Landslide Behavior Types*
4. Use *Monte Carlo Simulation* to estimate the annual probabilities of landslide displacements exceeding the asset condition state thresholds
5. Predict annual costs (maintenance & management effort; event-based costs) over the asset design life, and determine *Present Value of Lifecycle Cost*

## Pipeline Condition States & Costs (1)

- Annual costs would occur every year if an inspection, monitoring and maintenance program was in place (States A, B, and C)
- If detected, a transition to State D would trigger emergency actions that would include reverting the pipe back to a better condition state (a one-time event cost)
- A transition to State F would result in realization of failure costs (also a one-time event cost)

**TABLE 3. PIPELINE CONDITION STATES AND TYPICAL ACTIONS AND COSTS FOR LIFECYCLE COST MODELLING**

| Condition State | Description                           | Typical Actions if Condition State is Known  | Typical Annual or Event Cost |
|-----------------|---------------------------------------|--|------------------------------|
| A               | No definitive evidence of pipe strain | Infrequent visual inspection or aerial patrol  | <\$1k/yr                     |
| B               | Strain well below plastic limit       | Visual inspection and IMU  | \$1k to \$10k/yr             |
| C               | Strain approaching plastic limit      | Frequent inspections and IMU; detailed investigation; planned strain relief                | \$10k to \$1M/yr             |
| D               | Strain exceeding plastic limit        | Pipe shut-in; slope stabilization; emergency strain relief; re-route                       | \$1M to \$10M (event cost)   |
| F               | Loss of containment                   | Service outage; cleanup and repair; emergency strain relief; slope stabilization; re-route | >\$10M (event cost)          |

## Landslide Velocity Classes (2)

Modified from Cruden and Varnes (1996)

Defined in terms of an annual displacement (m) at a location of interest (total displacement over a cycle of seasons)

Estimated from field reconnaissance, remote sensing, instrumentation

Class 4+ includes any annual displacement exceeding 16 m

Each velocity class represented by a range, mean, and assumed left-triangular probability density function

**TABLE 1. MODIFIED LANDSLIDE VELOCITY CLASSIFICATION AFTER CRUDEN AND VARNES [3]**

| Class | Description     | Typical velocity | Proposed annual displacement criteria (m) | Proposed mean annual displacement (m) |
|-------|-----------------|------------------|---|---------------------------------------|
| 7     | Extremely rapid | >5 m/sec         |   |                                       |
| 6     | Very rapid      | >3 m/min         |   |                                       |
| 5     | Rapid           | >1.8 m/hr        |   |                                       |
| 4+    | Moderate        | >13 m/mo         | >16                                       | 64                                    |
| 3     | Slow            | >1.6 m/yr        | >1.6                                      | 6.4                                   |
| 2b    | Very slow       | >160 mm/yr       | >0.16                                     | 0.64                                  |
| 2a    | Very slow       | >16 mm/yr        | >0.016                                    | 0.064                                 |
| 1     | Extremely slow  | <16 mm/yr        | >0  | 0.005                                 |
| 0     | Dormant         | 0 mm/yr          | 0   | 0                                     |

Note: Class 4+ refers to all velocity classes Moderate or greater

## Predicting Displacement of a Slow-moving Landslides (3)

**Slope geometry** can change as a result of *slide movement*, surface erosion, toe erosion, human activity

**Cohesion and angle of friction** can change in response to *progressive failure*, weathering, changes in soil moisture, changes in *slide movement rate*

**Porewater pressure** can change in response to changes in rainfall, snow accumulation & melt, evapotranspiration (e.g. timber harvesting, forest fire), *formation of tension cracks and sag ponds*, *internal shearing*, external loads

## Need a Probabilistic Model

## Markov Chain models generate a velocity class probability distribution for each model timestep (3)

$$\begin{matrix} [ P_0, P_1, P_{2a}, P_{2b}, P_3, P_{4+} ] & \times & \left[ \begin{matrix} \text{Matrix of} \\ \text{Transition} \\ \text{Probabilities} \end{matrix} \right]^n & = & [ P_0, P_1, P_{2a}, P_{2b}, P_3, P_{4+} ] \end{matrix}$$

**Initial Velocity Class Probability Distribution**      **Transition Matrix**      **Velocity Class Probability Distribution after 'n' timesteps**

After many timesteps these models converge on a limiting state probability distribution (long-term average)

**TABLE 2. PROPOSED LANDSLIDE BEHAVIOR TYPES AND CHARACTERISTICS FOR PRE-EXISTING SLOW-MOVING LANDSLIDES**

| Behavior Type   | Type A                                 | Type B  | Type C   | Type D   | Type E   |
|---|--|---|--|--|--|
| Typical geology   | Relatively intact shales, mudstones    | Relatively intact shales, mudstones, residual soils, over-consolidated glacial deposits | Relatively intact glacial deposits, colluvium derived from shales, mudstones, residual soil and glacial deposits | Colluvium derived from shales, mudstones, residual soil and glacial deposits           | Colluvium derived from shales, mudstones, residual soil and glacial deposits           |
| Typical failure mechanism   | Translational block slides and spreads | Translational block slides and spreads  | Translational block slides and spreads, rotational slides, complex earth slides-earth flows                      | Translational slides, rotational slides, earth flows, complex earth slides-earth flows | Translational slides, rotational slides, earth flows, complex earth slides-earth flows |
| Typical inclination of basal shear surface  | Sub-horizontal (0 to 5 degrees)        | Sub-horizontal (0 to 5 degrees)   | Similar to the residual friction angle   | Similar to the residual friction angle   | Sub-parallel to the ground surface   |
| Typical toe condition   | No toe erosion                         | Toe erosion usually absent  | Toe erosion may be active  | Toe erosion often active   | Toe erosion almost always active   |
| Long-term annual probability of Class 4+ velocities   | 1 in 80,000                            | 1 in 17,000   | 1 in 3,000   | 1 in 750   | 1 in 250   |
| Assumed limiting state velocity class distribution; (assumed average annual displacement for each velocity class in brackets) |  |   |  |  |  |
| 0 (0 m)   | 79.2%                                  | 52.2%   | 32.6%  | 19.1%  | 12.0%  |
| 1 (0.005 m)   | 19.0%                                  | 43.6%   | 57.7%  | 58.4%  | 49.8%  |
| 2a (0.064 m)  | 1.6%                                   | 3.8%  | 8.7%   | 19.6%  | 28%  |
| 2b (0.64 m)   | 0.2%                                   | 0.3%  | 0.8%   | 2.3%   | 7.9%   |
| 3 (6.4 m)   | 0.02%                                  | 0.06%   | 0.19%  | 0.47%  | 1.90%  |
| 4+ (64 m)   | 0.001%                                 | 0.006%  | 0.034%   | 0.13%  | 0.42%  |
| Mean annual displacement  | 0.005 m                                | 0.015 m   | 0.05 m   | 0.15 m   | 0.50 m   |

# Landslide & Pipeline Condition States (3, 4)

## Model Outputs – Velocity Class Probabilities

| Markov Chain Velocity Class Probability Distributions |         |         |          |          |         |          |
|---|---------|---------|----------|----------|---------|----------|
| Year  | Class 0 | Class 1 | Class 2a | Class 2b | Class 3 | Class 4+ |
| 0   | 0       | 0.67    | 0.33     | 0        | 0       | 0        |
| 1   | 0.00224 | 0.67272 | 0.32086  | 0.00356  | 0.00055 | 0.00006  |
| 2   | 0.00446 | 0.67535 | 0.31254  | 0.00644  | 0.00108 | 0.00014  |
| 3   | 0.00666 | 0.67788 | 0.30491  | 0.00877  | 0.00157 | 0.00021  |
| 4   | 0.00883 | 0.68032 | 0.29788  | 0.01067  | 0.00202 | 0.00029  |
| 5   | 0.01098 | 0.68266 | 0.29136  | 0.01221  | 0.00243 | 0.00036  |

**FIGURE 2:** EXAMPLE MARKOV CHAIN MODEL OUTPUTS FOR TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 25 MM PER YEAR

## Monte Carlo Simulation

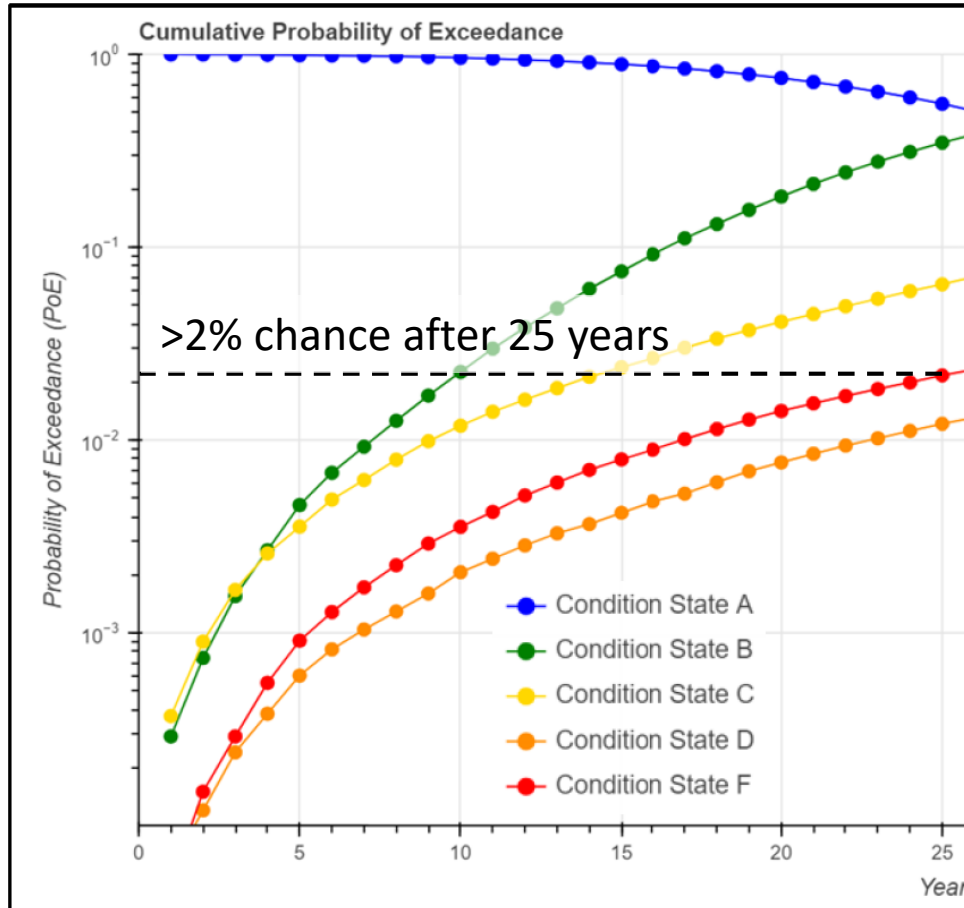

- 100,000 trials for each year
- For each trial:
  - Randomly sample model output, estimate displacement for each trial
  - Subtract displacement from remaining pipe capacity
  - Determine pipe condition state
- Determine pipeline condition state probabilities based on outcomes for all trials

## Pipeline Condition States (4)

From FEA: transition to State B after 100 mm; State C after 250 mm; State D after 750 mm; State F after 1,500 mm

**FIGURE 3:** PIPELINE CONDITION STATE MODELLING OUTPUTS FOR TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 5 MM PER YEAR

**FIGURE 4:** PIPELINE CONDITION STATE MODELLING OUTPUTS FOR TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 25 MM PER YEAR

## Lifecycle Cost Models (5) – Purely Reactive

**TABLE 3. PIPELINE CONDITION STATES AND TYPICAL ACTIONS AND COSTS FOR LIFECYCLE COST MODELLING**

|          | Condition State | Description                           | Typical Actions if Condition State is Known  | Typical Annual or Event Cost |
|----------|-----------------|---------------------------------------|--|------------------------------|
|          | A               | No definitive evidence of pipe strain | Infrequent visual inspection or aerial patrol  |                              |
| 100 mm   | B               | Strain well below plastic limit       | Visual inspection and IMU  |                              |
| 250 mm   | C               | Strain approaching plastic limit      | Frequent inspections and IMU; detailed investigation; planned strain relief                |                              |
| 750 mm   | D               | Strain exceeding plastic limit        | Pipe shut-in; slope stabilization; emergency strain relief; re-route                       |                              |
| 1,500 mm | F               | Loss of containment                   | Service outage; cleanup and repair; emergency strain relief; slope stabilization; re-route | \$50M                        |

**TABLE 4. LIFECYCLE COST MODELLING ASSUMPTIONS**

| Item  | Assumptions                                      |
|---|--|
| Pipeline Design Life  | 25 years   |
| Discount Rate   | 3%   |
| Initial Pipeline Condition State Displacement Thresholds (mm) | A/B=100 mm; B/C=250 mm; C/D=750 mm; D/F=1,500 mm |
| Un-planned Outage and Strain Relief/Repair Cost               | \$5M   |
| Cost of Pipeline Rupture While Operating                      | \$50M  |
| Do Nothing (No Inspection or Monitoring)                      | No cost realized unless pipe fails (State F)     |

## Lifecycle Cost Models (5) – Purely Reactive

**FIGURE 5:** ESTIMATED LIFECYCLE COSTS FOR PIPELINE CROSSING TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 5 MM PER YEAR

**FIGURE 6:** ESTIMATED LIFECYCLE COSTS FOR PIPELINE CROSSING TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 25 MM PER YEAR

## Modelling Benefits of Management Approaches

- Management actions will provide opportunity for early detection of change (landslide velocity or pipeline condition state)
  - Some actions will have a higher probability of successful detection than others (e.g. visual inspection v. slope inclinometer)
  - Some actions will lead to earlier or more frequent detection (e.g. slope inclinometer v. real-time SAA)
- Early detection will allow for intervention
  - Slope stabilization (reduce landslide movement rate)
  - Planned or un-planned strain relief (re-set condition state)
  - Shut-in pipeline (reduce rupture impact and cost)
  - Re-locate pipeline (avoid hazard)
- Detection and intervention will take time
  - The shorter the time interval, the lower the likelihood that a deterioration to pipeline condition state D or F will occur
- Simplified modelling approach:
  - increase remaining pipeline displacement capacity as a function of the probability and timing of successful detection and intervention
  - re-set pipeline condition state at regular intervals if known through IMU analysis

## Costs and Benefits of Annual Visual Inspections

### Inspection Costs

- ~\$1,500/yr if part of a larger inspection program
- \$5M for un-planned strain relief (State D)
- \$50M if rupture occurs (State F)

### Benefits

- From experience, good success of detecting landslide displacement >50 mm/yr from visual inspection
- Landslide displacement was detected from visual inspection in about 50% of critical strain hits identified from IMU
- Increase landslide displacement required to transition to State D or F by ~50%

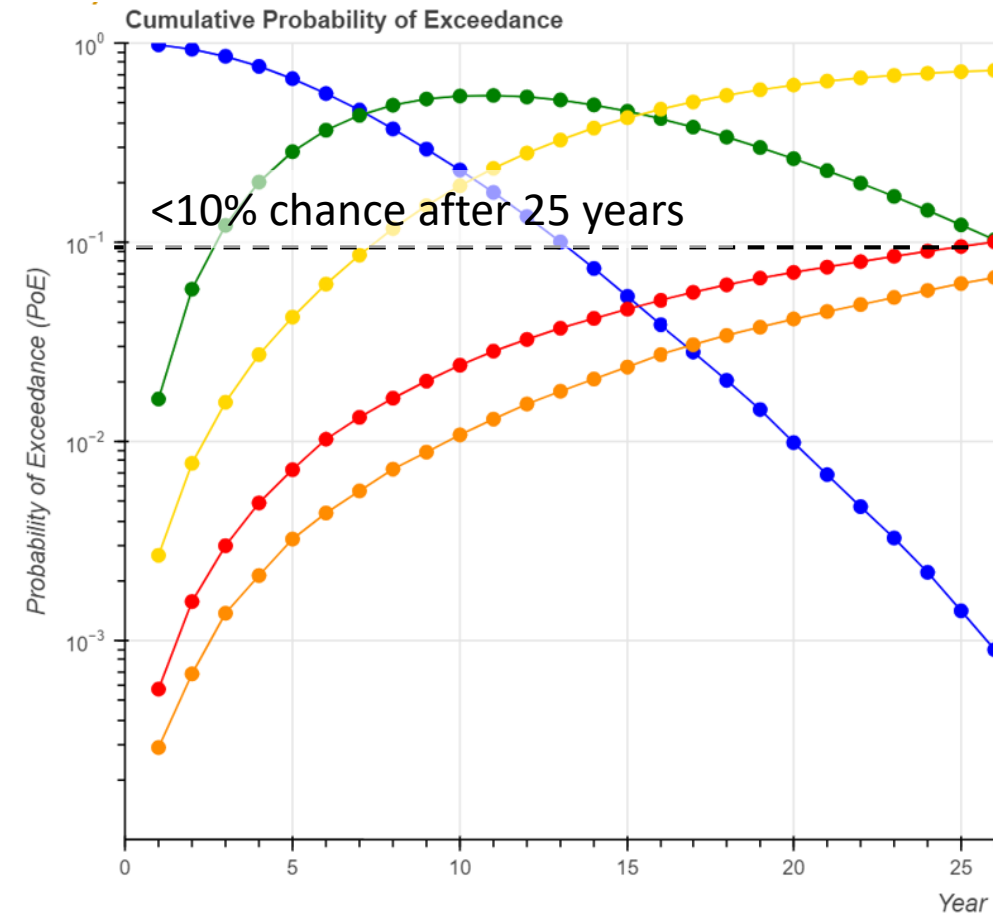

## Example: Annual Visual Inspections

From FEA: transition to State B after 100 mm; State C after 250 mm; State D after 1,125 mm; State F after 2,250 mm

Initial Velocity = 5 mm/yr

Initial Velocity = 25 mm/yr

## Lifecycle Cost Models – Annual Inspections

**FIGURE 5:** ESTIMATED LIFECYCLE COSTS FOR PIPELINE CROSSING TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 5 MM PER YEAR

**FIGURE 6:** ESTIMATED LIFECYCLE COSTS FOR PIPELINE CROSSING TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 25 MM PER YEAR

## Costs and Benefits of Inspections + IMU

### IMU Costs

- Assume IMU is already being collected ~every 5 years as part of integrity program
- Cost of detailed geotechnical assessment of IMU ~\$10k (~\$2k/yr)
- No additional cost if pipe is found to be in State A or B
- Planned strain relief (~\$1.5M) in State C

### IMU Benefits

- Re-set worst pipeline condition state to State C every 5 years

## Inspections + IMU

From FEA: transition to State B after 100 mm; State C after 250 mm; State D after 1,125 mm; State F after 2,250 mm

Initial Velocity = 5 mm/yr

Initial Velocity = 25 mm/yr

## Inspections + IMU

**FIGURE 5:** ESTIMATED LIFECYCLE COSTS FOR PIPELINE CROSSING TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 5 MM PER YEAR

**FIGURE 6:** ESTIMATED LIFECYCLE COSTS FOR PIPELINE CROSSING TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 25 MM PER YEAR

## Costs and Benefits of Inspections + IMU + Real-time Monitoring

### Real-time Monitoring Costs

- ~\$25,000/yr

### Real-time Monitoring Benefits

- High likelihood of successful detection and response within a 3-month period (1/4 year)
- Increase landslide displacement required to transition to State D or F by a factor of 4

## Inspections + IMU + Real-time Monitoring

**FIGURE 5:** ESTIMATED LIFECYCLE COSTS FOR PIPELINE CROSSING TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 5 MM PER YEAR

**FIGURE 6:** ESTIMATED LIFECYCLE COSTS FOR PIPELINE CROSSING TYPE C LANDSLIDE WITH AN INITIAL VELOCITY OF 25 MM PER YEAR
